# Orbital Mechanics

## Module 2: Orbit representation

Juan Luis GONZALO GOMEZ, Lorenzo GIUDICI, Camilla COLOMBO

Department of Aerospace Science and Technology, Politecnico di Milano

Academic year 2021/22

# Module Contents

## Orbit representation

### ■ Orbit representation

- Cartesian and Keplerian elements
- Ephemerides
- SGP models and TLEs
- Online resources
- References

### ■ Ground track

- Definition, angles, geometrical properties
- Repeating ground tracks
- **Exercise 1:** Computation of ground tracks
- **Exercise 2:** Design of repeating ground tracks
- Ground tracks with perturbations
- **Exercise 3:** Ground tracks with  $J_2$

**POLITECNICO**  
MILANO 1863

# ORBIT REPRESENTATION

# Cartesian and Keplerian elements

## Basic orbit representation

- The most common representations for the state of an orbiting body are the **Cartesian coordinates** and the **Keplerian elements** [1]:
  - **Cartesian coordinates**  $\mathbf{s} = [\mathbf{r}, \mathbf{v}]$ . Position  $\mathbf{r}$  and velocity  $\mathbf{v}$  at a given time  $t$ .
  - **Keplerian elements**  $\boldsymbol{\alpha} = [a, e, i, \Omega, \omega, M]$ . Based on a geometric description of the conic:
    - $a$  and  $e$  give the geometry of the planar conic.
    - $i$ ,  $\Omega$ , and  $\omega$  give the orientation of the conic in space (Euler angles).
    - $M$  (or equivalently, true anomaly  $f$ ) gives the object's position in the orbit.  $M$  and  $f$  are related through Kepler's equation.
- It is possible to convert between both [1]:
  - You will need `kep2car` and `car2kep` functions for the labs.
  - Be careful with singularities at  $e = 0$  and  $i = 0$  deg.
  - Test your functions converting a set of elements back and forth and checking if you recover the original value:  $\mathbf{s} \rightarrow \boldsymbol{\alpha} \rightarrow \tilde{\mathbf{s}} = \mathbf{s}$ .

[1] Curtis, H. D.. *Orbital mechanics for engineering students*, Butterworth-Heinemann , 2014

# Cartesian and Keplerian elements

## Osculating orbit and singularities

- Strictly, **Keplerian elements are defined for Keplerian orbits (2BP)**

- $[a, e, i, \Omega, \omega]$  constant,  $M$  changes in time. That is, the orbit remains constant, and the body moves along it.
  - In the presence of perturbations, the orbit changes slowly in time.

**Osculating orbit:** Keplerian orbit that the object would have around the central body at a particular time instant if perturbations were absent.

**Osculating elements:** Keplerian elements of the osculating orbit. They evolve in time.

- Keplerian elements have 2 singularities:

- **Zero inclination:** The line of nodes is not defined.  $\Omega$  can take an arbitrary value, the angle of the apse line with the  $X$  axis is  $\Omega + \omega$ .
  - **Circular orbit:** The line of apses is not defined.  $\omega$  can take an arbitrary value, the angular position of the body with the line of nodes is  $\omega + f$ .

# Ephemerides

## Locating objects in space

- A table of the coordinates of celestial bodies as a function of time is called an **ephemeris** [1].
  - Can be provided in the form of a look-up table, polynomial fittings, TLEs, etc.
  - Computed from astronomical observations and precise orbit propagation.
  - Importance of the **reference time** (epoch of the ephemeris).
- We will make an overview of one of the most common sources of ephemerides: the **Simplified General Perturbation (SGP) models** and the **Two-Line Elements (TLE)**.
- Other ephemerides will be used in future labs (Matlab functions available in WeBeep).

[1] Curtis, H. D.. *Orbital mechanics for engineering students*, Butterworth-Heinemann , 2014

# Simplified General Perturbation models

## Overview

- **Simplified General Perturbation (SGP) models:**
  - Analytical methods for propagating the orbital state of a satellite or debris, **taking as input some ad-hoc mean elements**.
  - They include expressions for the **secular (linear), long-periodic and short-periodic (oscillatory) evolutions**, depending on the perturbations included.
- The US Air Force began development of their SGP model series in the 1960s:
  - Five different models: SGP, SGP4/SDP4, and SGP8/SDP8.
  - SGP/SGP4/SPG8 for close-Earth objects (period <225 minutes), SDP4/SDP8 for deep-space objects (period  $\geq$  225 minutes).
  - Most used one is SGP4/SDP4.
  - **Mean elements distributed as Two-Line Element (TLE) sets.**
  - SGP4/SDP4 was documented in Spacetrack Report #3, to promote compatibility in the operational community.

# Simplified General Perturbation models

## Two-line elements

- NORAD (North American Aerospace Defense Command) provides the TLEs for SGP4/SDP4.
  - TLEs for SGP/SGP8/SDP8 can be derived from them (some fields are included only for this purpose).
- TLEs are computed from observations and orbit determination procedures.
  - Exact data and models used are classified information.
  - A single TLE allows to propagate the orbital state for a **limited time range** around the TLE epoch (accuracy degradation).
- Data is stored in two different lines (hence the name):
  - Originally in 80-column punch cards.
  - Currently in 70-column ASCII files.
  - They are made publicly available through Space-Track, but not all objects can be queried (e.g., classified satellites are excluded).
- **The orbital elements in the TLEs are averaged mean values, not the osculating elements at the epoch of the TLE. Do not use them directly.**

# Simplified General Perturbation models

## Two-line elements – Line 1

The image shows the homepage of the CelesTrak website. At the top is the CelesTrak logo, featuring a blue star with a black outline and a small yellow dot above it, next to the text "CELESTRAK™ SINCE 1985". Below the logo is a text box with a light blue background containing a message about GP data availability. Underneath is a banner for "CelesTrak Orbit Visualization" with a "Launch Orbit Visualization" button. The main content area has a dark background with a starry field. It features a sidebar with links like "Follow CelesTrak on Twitter @TSKelso", "NORAD Two-Line & GP Element Sets", "Online Satellite Catalog (SATCAT)", and "Space Data". The central part of the page contains news items and links related to orbital events and data sets.

<https://celestak.com/>

- Created and maintained by **Dr. T.S. Kelso**.
  - Originally introduced in 1985 to make TLEs electronically available (NASA was providing them as printed bulletins).
- Contains a lot of **useful information**:
  - Current TLEs for non-classified satellites, organized by types of satellites/missions.
  - Historical TLEs archive for selected objects.
  - Satellite catalogue (SATCAT).
  - Documentation and Q&A (including a detailed description of TLEs).
  - Software.
  - Others: GPS data, space weather data, etc.
  - Orbit visualization tool.

# Space-Track

# Space-Track

<https://www.space-track.org>

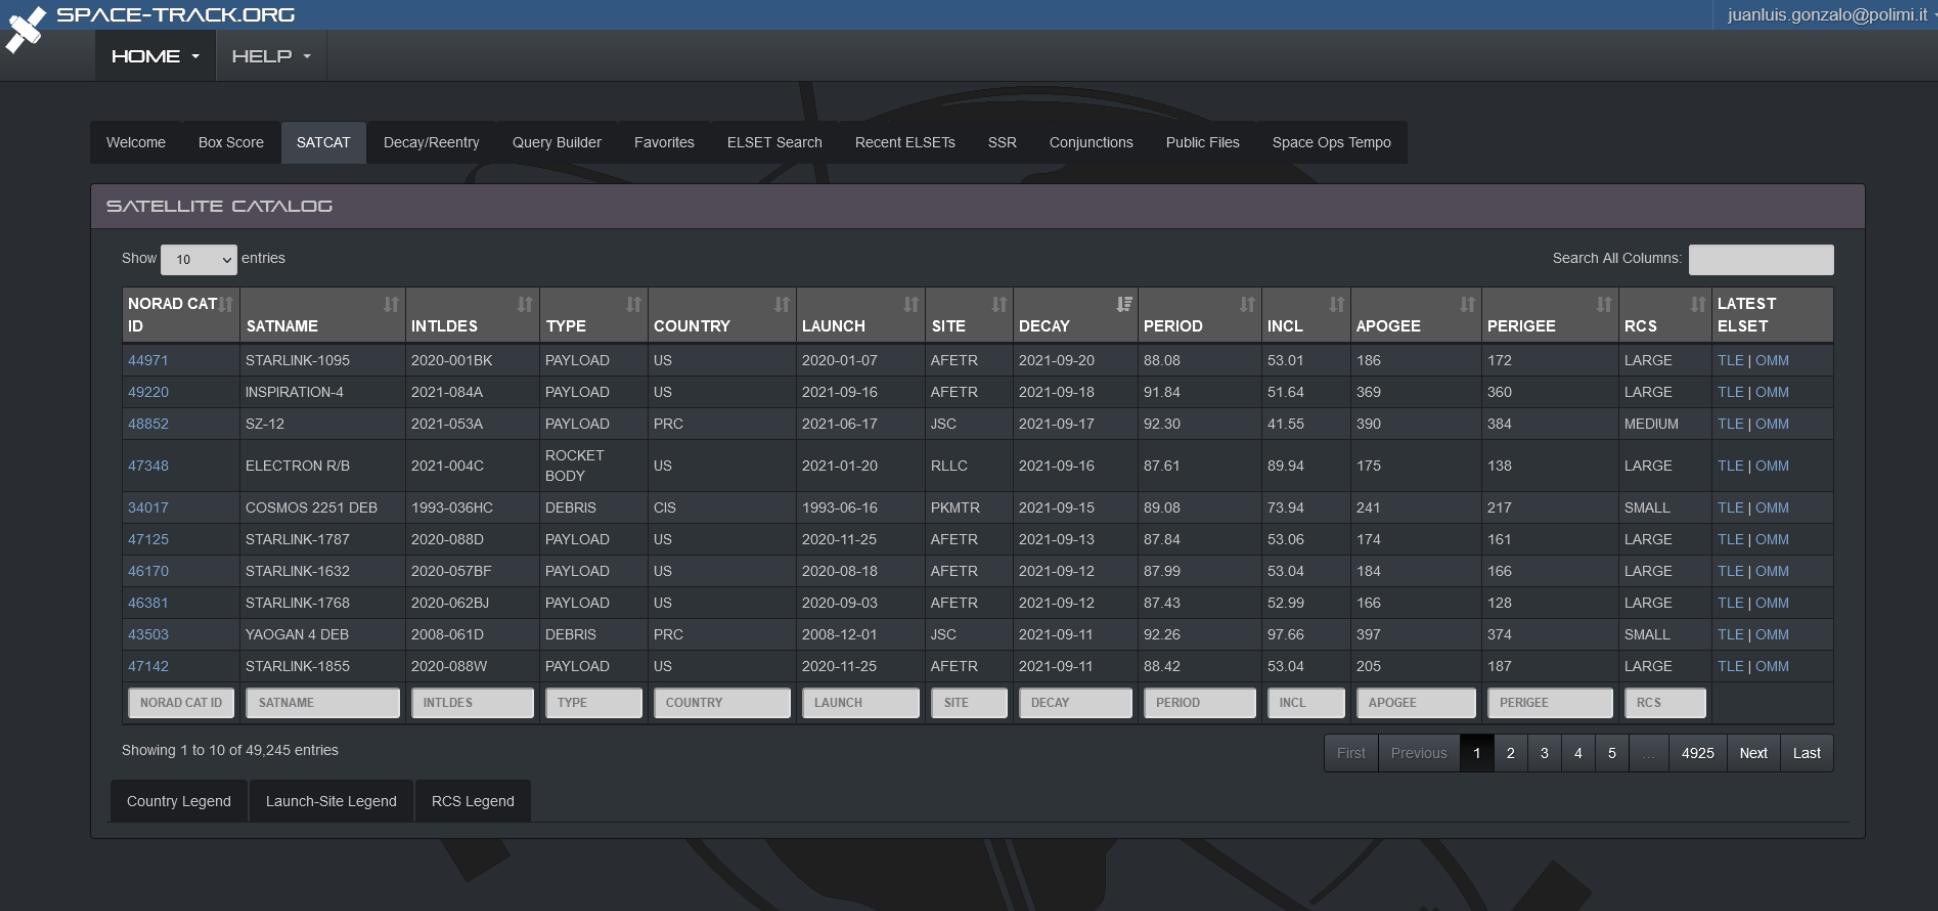

- **TLE information published by USSPACECOM/NORAD:**

- Objective: *promoting a safe, stable, sustainable, and secure space environment through Space Situational Awareness information sharing.*
- Includes a Windows/Linux implementation of SGP4.
- API for automatic queries.
- Information about decay/reentry of satellites.
- Information about conjunctions (close approaches) between space debris.
- Requires an account.
  - You should have no problem in getting an account using your university email.

# Space-Track

## SATCAT

- Satellite catalog (SATCAT) can be filtered, ordered and queried for different fields.

The screenshot shows the Space-Track.org website's SATCAT page. The top navigation bar includes links for HOME, HELP, Welcome, Box Score, SATCAT (which is selected), Decay/Reentry, Query Builder, Favorites, ELSET Search, Recent ELSETs, SSR, Conjunctions, Public Files, and Space Ops Tempo. The main content area is titled "SATELLITE CATALOG" and displays a table of satellite data. The table has 17 columns: NORAD CAT ID, SATNAME, INTLDES, TYPE, COUNTRY, LAUNCH, SITE, DECAY, PERIOD, INCL, APOGEE, PERIGEE, RCS, and LATEST ELSET. The data is sorted by NORAD CAT ID. The table contains 10 entries, with the first few rows shown below:

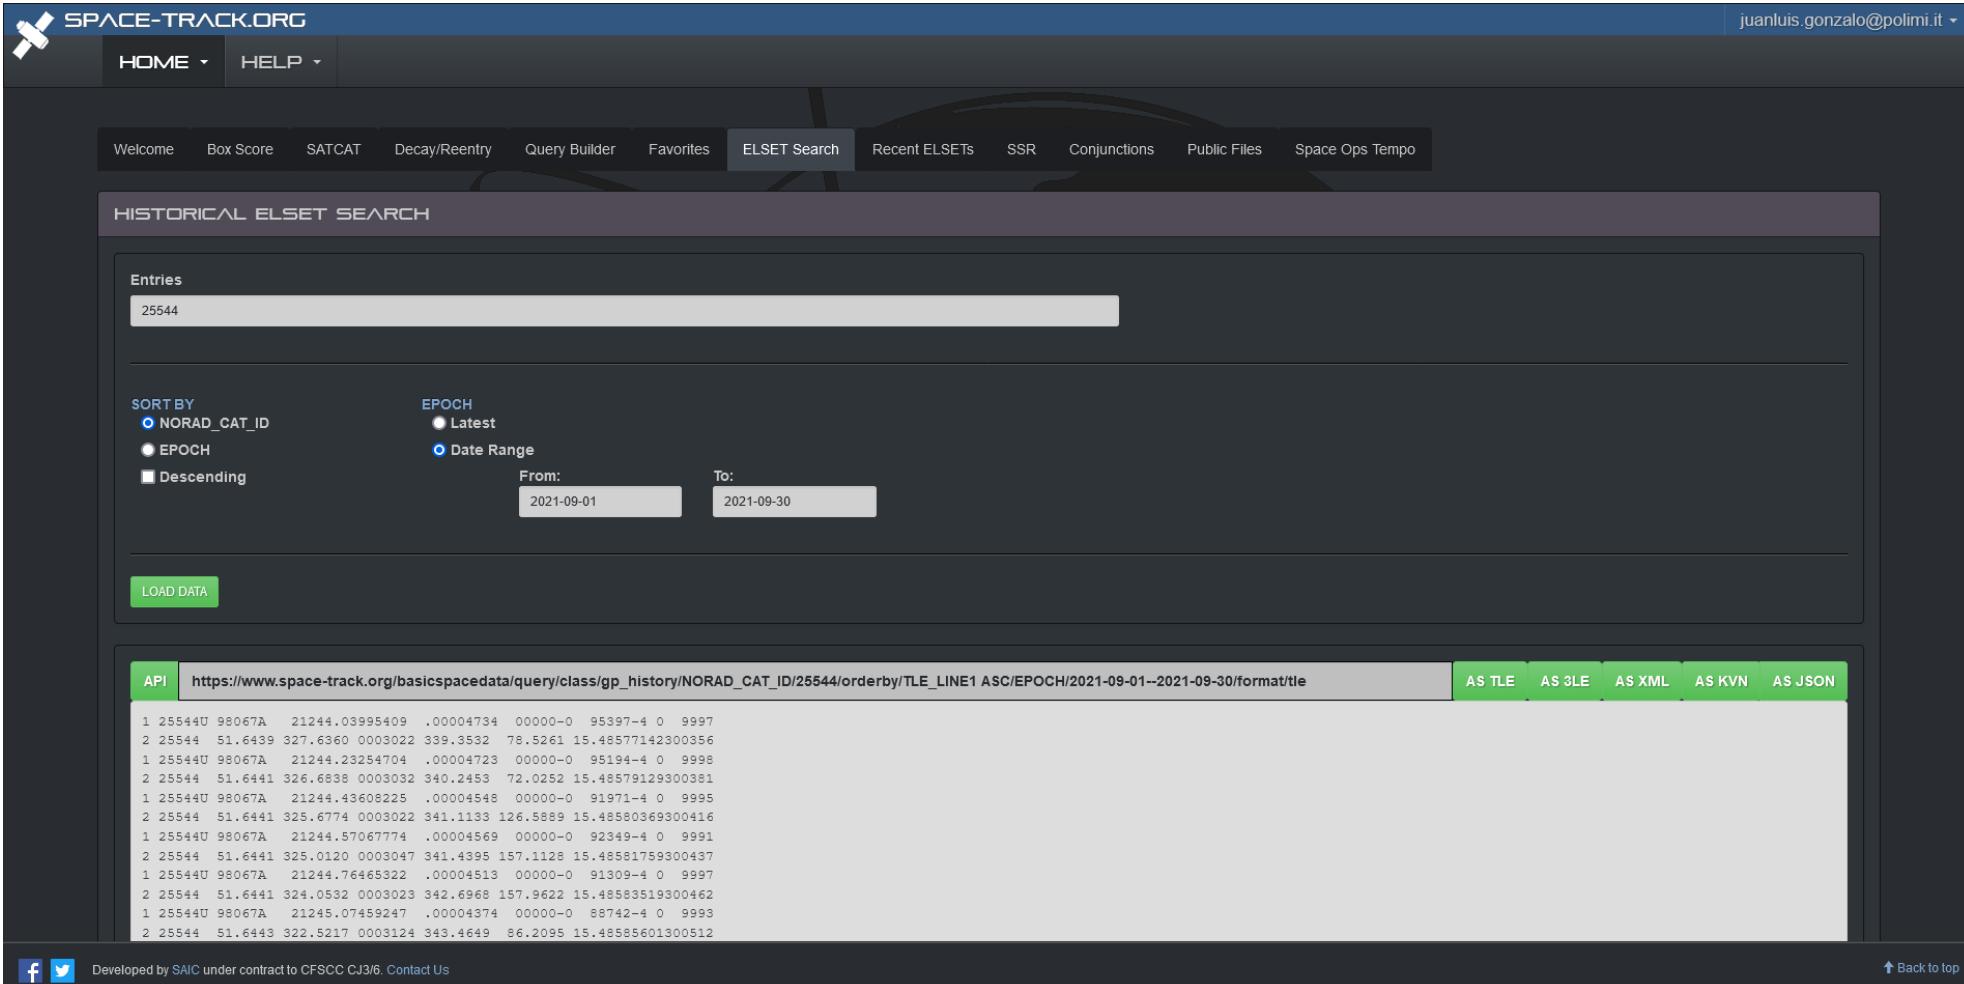

NORAD CAT ID	SATNAME	INTLDES	TYPE	COUNTRY	LAUNCH	SITE	DECAY	PERIOD	INCL	APOGEE	PERIGEE	RCS	LATEST ELSET

Below the table, there are buttons for NORAD CAT ID, SATNAME, INTLDES, TYPE, COUNTRY, LAUNCH, SITE, DECAY, PERIOD, INCL, APOGEE, PERIGEE, and RCS. At the bottom, it says "Showing 1 to 10 of 49,245 entries" and provides navigation links for First, Previous, Next, and Last. There are also legends for Country Legend, Launch-Site Legend, and RCS Legend.

# Space-Track

## ELSET Search

- Search of historical element sets (TLEs, 3LEs, Keplerian, ...) for given satellites and epoch ranges.

The screenshot shows the Space-Track.org website with the "ELSET Search" tab selected. The main search interface is titled "HISTORICAL ELSET SEARCH". It displays the entry number "25544" and allows sorting by "NORAD\_CAT\_ID" (selected) or "EPOCH" (Latest or Date Range), with an option for Descending order. The search parameters are set from "2021-09-01" to "2021-09-30". A green "LOAD DATA" button is present. Below the search form, an API endpoint is shown: `https://www.space-track.org/basicspacedata/query/class/gp_history/NORAD_CAT_ID/25544/orderby/TLE_LINE1 ASC/EPOCH/2021-09-01--2021-09-30/format/tle`. To the right of the API URL are download links for "AS TLE", "AS 3LE", "AS XML", "AS KVN", and "AS JSON". The bottom section of the screenshot shows the raw TLE data for satellite 25544, NORAD\_CAT\_ID 98067A, from September 1, 2021, to September 30, 2021.

# NASA/JPL HORIZONS

<https://ssd.jpl.nasa.gov/horizons/>

- NASA/JPL HORIZONS is a **solar system data and ephemeris computation service**:
  - Maintained by the Solar System Dynamics Group of the Jet Propulsion Laboratory (JPL).
  - Provides access to key solar system data.
  - Computes highly accurate ephemerides for solar system objects (1,134,533 asteroids, 3,760 comets, 205 planetary satellites, 8 planets, the Sun, L1, L2, select spacecraft, and system barycenters).
  - Few Earth-orbiting objects are included in the database, but users can provide their own set of TLEs (i.e., we can use it as a SGP4 implementation).
  - Full access through remote command-line interface or email (submitting batch-style input files).
  - A web interface is available (providing nearly all capabilities).

<https://ssd.jpl.nasa.gov/horizons/>

- Settings for the web interface
  - **Ephemeris type:** Osculating Orbital Elements.
  - **Target body:** Select a satellite from the database, or provide up to 750 sets of SGP4/SDP4 TLEs in standard form (option “Specify a target using TLEs” in the dropdown menu).
  - **Coordinate Center:** Geocentric (code 500) for Earth-orbiting objects.
  - **Time Specification:** Initial time, final time, and step size. Remember that the earliest initial time and latest final time are limited by the available data (particularly, each set of TLEs only allows to propagate a few days before and after its epoch).
  - **Table Settings:** Available options depend on the Ephemeris type. Remember to choose adequate reference frame (ICRF), reference plane (equatorial), and units (km and km/s). To import the results into Matlab and other tools, it is strongly recommended to set output to CSV format.
  - **Generate Ephemeris:** Click to generate and visualize the ephemeris. The results can then be downloaded as a plaintext file clicking on “Download Results”.

# GROUND TRACK

# Ground Track

## Definition

**Ground track:** *Projection of a satellite's orbit onto the Earth's surface [1].*

- Neglecting Earth's oblateness, it can be plotted as the trace left on the planet's surface by the line connecting the centre of the Earth and the satellite as it travels its orbit.
- At each time  $t$ , the ground track point is located by its **latitude  $\phi$**  and **longitude  $\lambda$**  relative to the **rotating Earth**.

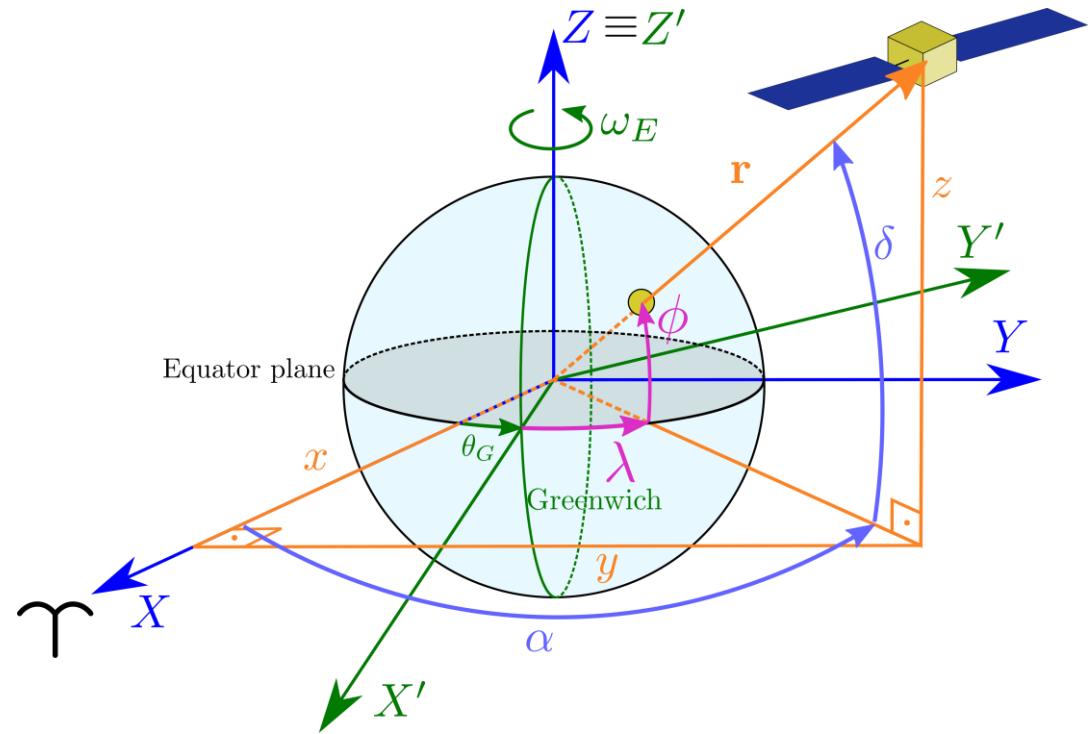

$$\begin{aligned}
 a &= 26600 \text{ km} \\
 e &= 0.74 \\
 i &= 63.4 \text{ deg} \\
 \Omega &= 50 \text{ deg} \\
 \omega &= 280 \text{ deg} \\
 f_0 &= 0 \text{ deg}^{\ddagger} \\
 30 \text{ orbits}
 \end{aligned}$$

$\ddagger$   $f$  denotes true anomaly

[1] Curtis, H. D.. *Orbital mechanics for engineering students*, Butterworth-Heinemann , 2014

# Ground Track

Angles for the ground track

$$\theta_G(t) = \theta_G(t_0) + \omega_E (t - t_0)$$

*Declination*

$$\delta = \text{asin} \frac{z}{r}$$

*Right ascension*

$$\alpha = \begin{cases} \text{acos} \frac{x/r}{\cos \delta} & \frac{y}{r} > 0 \\ 2\pi - \text{acos} \frac{x/r}{\cos \delta} & \frac{y}{r} \leq 0 \end{cases}$$

*Longitude*

$$\lambda = \alpha - \theta_G$$

*Latitude*

$$\phi = \delta$$

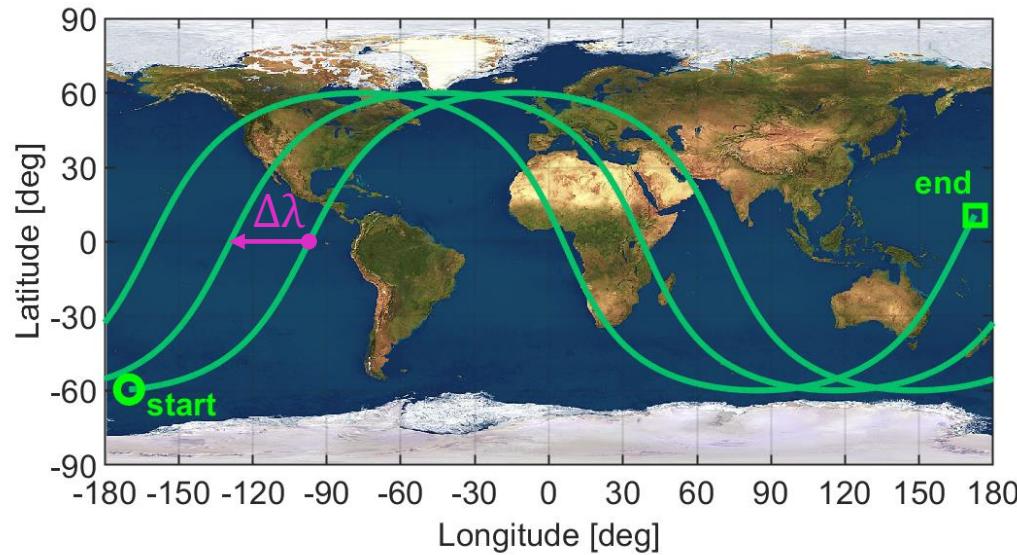

# Ground Track

## Geometrical properties

- For each orbital revolution, the ground track presents 2 *equator crossings*, one *maximum in latitude*, and one *minimum in latitude*.
- For the unperturbed two-body problem, the orbit remains constant. However, **the ground track advances westward** by an angle  $\Delta\lambda$  equal to Earth's rotation during one orbital period  $T$  of the satellite:

$$\Delta\lambda = T \omega_E$$

Earth's rotation velocity (eastwards):  $\omega_E = 15.04 \text{ deg/h}$

$a = 8350 \text{ km}$   
 $e = 0.19760$   
 $i = 60 \text{ deg}$   
 $\Omega = 270 \text{ deg}$   
 $\omega = 45 \text{ deg}$   
 $f_0 = 230 \text{ deg}$   
 3.25 orbits

# Ground Track

## Repeating ground tracks

- A ground track will repeat itself after  $k$  revolutions of the satellite and  $m$  rotations of the planet if the total ground track drift  $k\Delta\lambda$  is equal to the corresponding planet rotation  $m2\pi$ :

$$k \Delta\lambda = m 2\pi \Rightarrow \frac{\Delta\lambda}{2\pi} = \frac{m}{k} \quad \text{with } k, m \in \mathbb{N}$$

- Substituting  $\Delta\lambda = T\omega_E$  and operating, we see that this is equivalent to imposing that *the ratio of the satellite's orbital period  $T$  and Earth's rotational period  $T_E = 2\pi/\omega_E$  is a rational number*:

$$\frac{T}{T_E} = \frac{m}{k} \quad \text{with } k, m \in \mathbb{N}$$

- Or expressed in terms of the satellite's mean motion  $n = 2\pi/T$  and Earth's rotation velocity  $\omega_E$ :

$$\frac{\omega_E}{n} = \frac{m}{k} \quad \text{with } k, m \in \mathbb{N}$$

# Ground Track

## Repeating ground tracks

- Therefore, **repeating ground tracks can be obtained by choosing an orbit with a period  $T$  such that:**

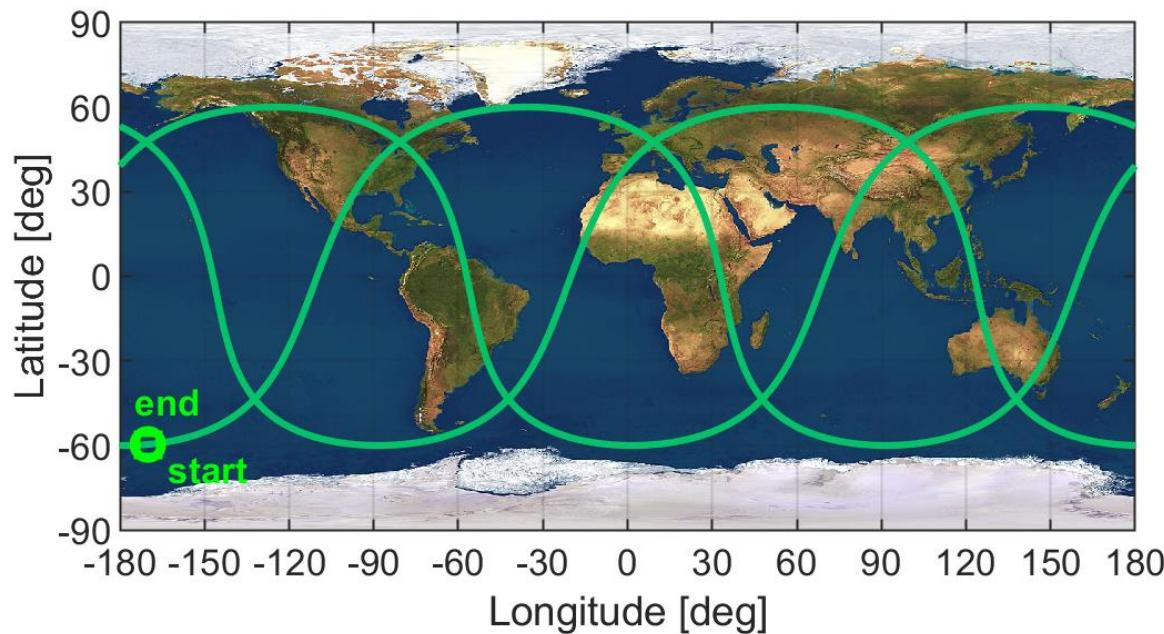

$$T = T_E \frac{m}{k} = \frac{2\pi m}{\omega_E k}$$

- Or equivalently, with a mean motion  $n$  such that:

$$n = \omega_E \frac{k}{m}$$

- Keep in mind that period  $T$  and mean motion  $n$  only depend on the semimajor axis  $a$ :

$$n = \frac{2\pi}{T} = \sqrt{\frac{\mu}{a^3}}$$

$a = 16733.65$ km	$\omega = 45$ deg
$e = 0.19760$	$f_0 = 230$ deg
$i = 60$ deg	$k = 4$
$\Omega = 270$ deg	$m = 1$

# Exercise 1: Computation of ground tracks

## Exercise 1: Computation of ground tracks

1. Implement a function `groundTrack` that computes the ground track of an orbit

- **Inputs:**

- State of the orbit at the initial time (either in Cartesian or Keplerian elements)
- Longitude of Greenwich meridian at initial time
- Vector of times at which the ground track will be computed
- Other inputs that you consider useful (e.g.,  $\omega_E$ ,  $\mu$ ,  $t_0$ )

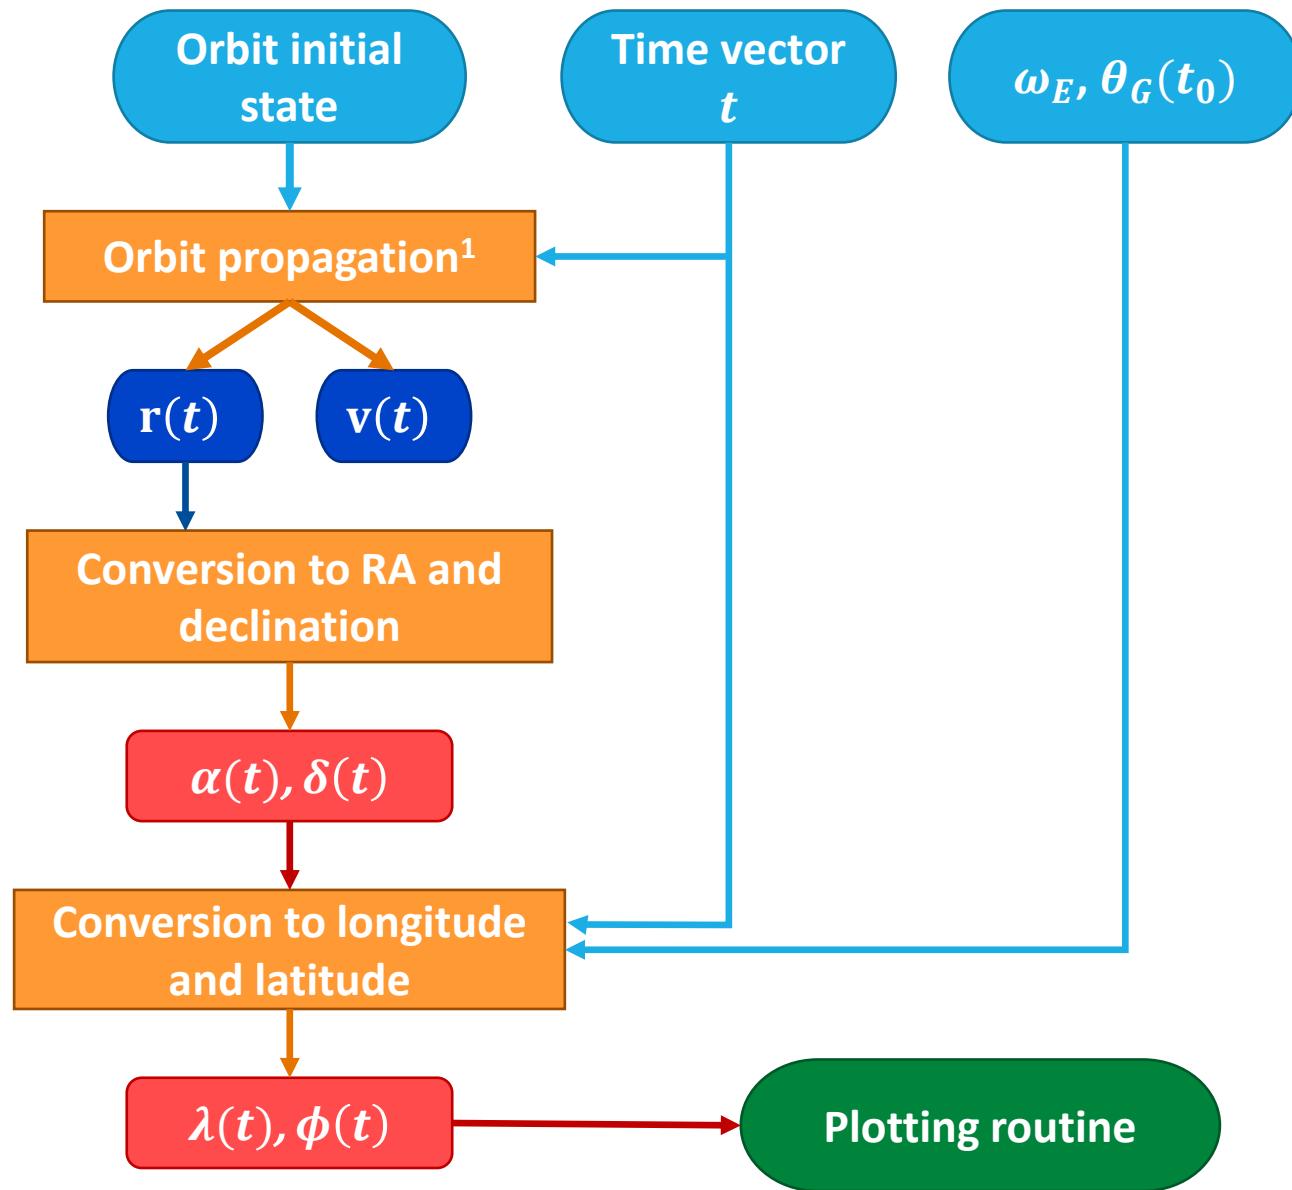

- **Outputs:**

- `alpha`: right ascension in Earth Centred Equatorial Inertial frame
- `delta`: declination in Earth Centred Equatorial Inertial frame
- `lon`: longitude with respect to rotating Earth (0 deg at Greenwich meridian)
- `lat`: latitude with respect to rotating Earth

# Exercise 1: Computation of ground tracks

## Flow diagram

For numerical orbit propagation<sup>1</sup>, you can reuse the code from **Module 1**.

<sup>1</sup> **Orbit propagation**: prediction of a body's orbital characteristics at a future date given the current orbital characteristics.

# Exercise 1: Computation of ground tracks

## Exercise 1: Computation of ground tracks

2. Plot the ground track for the following orbits:
  1.  $a = 8350 \text{ km}$ ,  $e = 0.1976$ ,  $i = 60 \text{ deg}$ ,  $\Omega = 270 \text{ deg}$ ,  $\omega = 45 \text{ deg}$ ,  $f_0 = 230 \text{ deg}$  (taken from [1], Example 4.12)
  2. A Molniya orbit with  $a = 26600 \text{ km}$ ,  $e = 0.74$ ,  $i = 63.4 \text{ deg}$ ,  $\Omega = 50 \text{ deg}$ ,  $\omega = 280 \text{ deg}$ ,  $f_0 = 0 \text{ deg}$
  3. Three circular LEO orbits with altitude 800 km,  $\Omega = 0 \text{ deg}$ ,  $\omega = 40 \text{ deg}$ ,  $f_0 = 0 \text{ deg}$ , and different inclinations: 0 deg , 30 deg , and 98 deg

### Data:

$\mu_{\oplus}$  and  $R_{\oplus}$  from `astroConstants.m` (identifiers 13, and 23, respectively)  
 $\omega_E = 15.04 \text{ deg/h}$      $\theta_G(t_0) = 0 \text{ deg}$

[1] Curtis, H. D.. *Orbital mechanics for engineering students*, Butterworth-Heinemann , 2014

# Exercise 1: Computation of ground tracks

## Hints

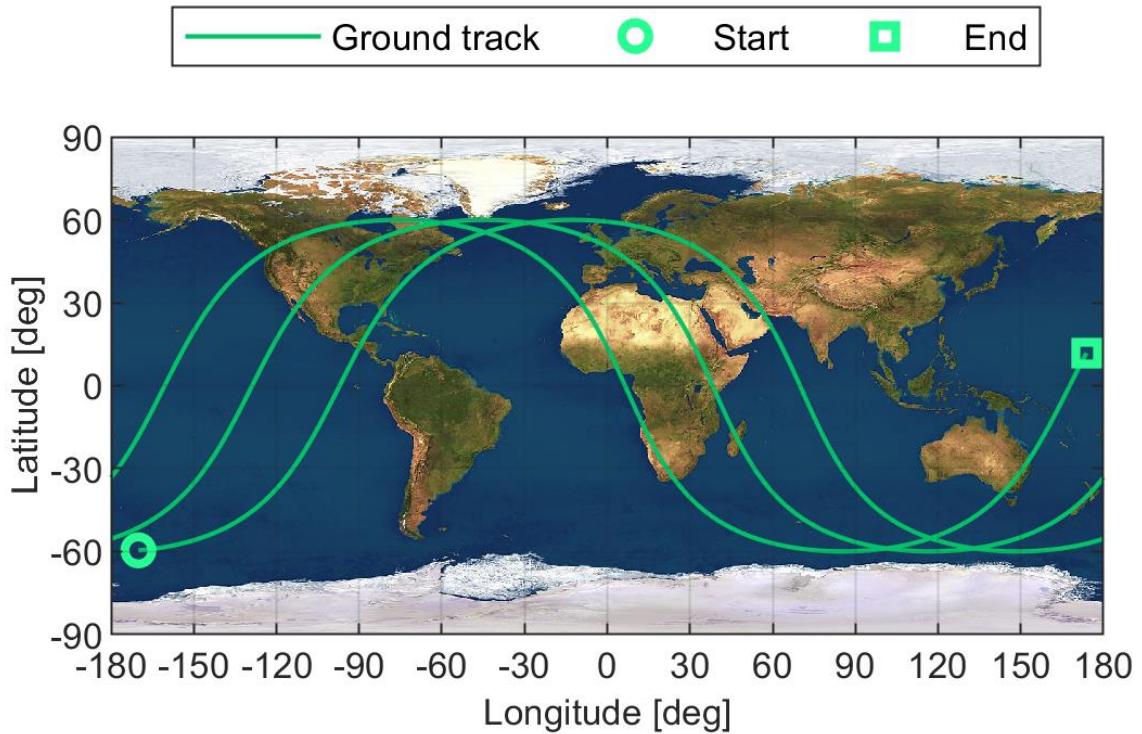

- **Radians** are more convenient for calculations, while **degrees** are better for graphical representation.
- **Longitude  $\lambda$**  has to be reduced to the 360 deg angular range chosen for the ground tracks (e.g., [ -180, 180 ] deg or [ 0, 360 ] deg). Consequently, the ground track plot will be discontinuous in  $\lambda$  at the boundaries of the angular range.

To avoid having horizontal lines connecting the points before and after the discontinuity:

- Easiest way is to change the plot style, removing the line connecting the data points and using a marker for each point instead. That is, setting 'LineStyle' to 'none' and 'Marker' to '.' (high number of points required to get a continuous path).
- If instead you want to keep the line connecting the data points, you can introduce NaN values in your data arrays separating the points before and after the discontinuity. Matlab does not connect the data points that include NaN values.
- If you want, you can add Earth's surface as background, using function `imread` to load the image as a matrix of colored pixels, and function `image` to plot it.
  - Check the **documentation center** for detailed information on how to use them.
- Don't forget to *adjust the limits for the plotting regions*, to *label the axes*, and to *add a legend* if more than one line is represented.

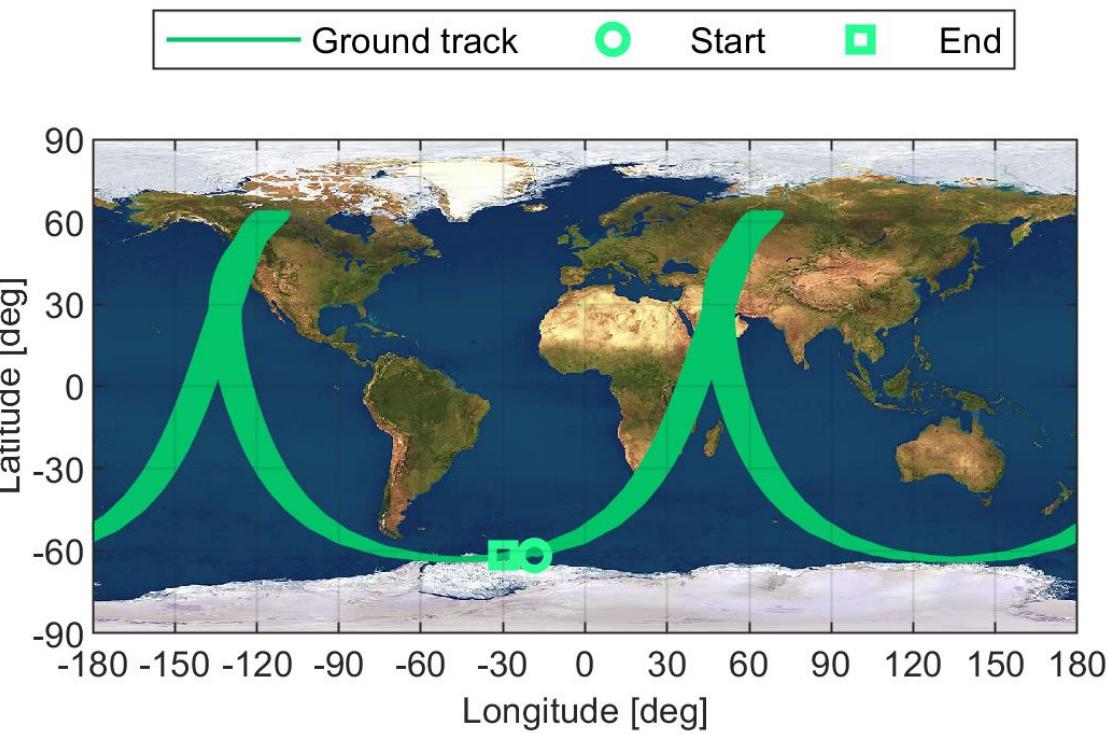

# Exercise 1: Computation of ground tracks

## Sample solutions

### Case 1

$a = 8350 \text{ km}$ ,  $e = 0.19760$ ,  $i = 60 \text{ deg}$   
 $\Omega = 270 \text{ deg}$ ,  $\omega = 45 \text{ deg}$ ,  $f_0 = 230 \text{ deg}$   
 $\theta_G(t_0) = 0 \text{ deg}$ , 3.25 orbits

### Case 2

$a = 26600 \text{ km}$ ,  $e = 0.74$ ,  $i = 63.4 \text{ deg}$   
 $\Omega = 50 \text{ deg}$ ,  $\omega = 280 \text{ deg}$ ,  $f_0 = 0 \text{ deg}$   
 $\theta_G(t_0) = 0 \text{ deg}$ , 30 orbits

# Exercise 1: Computation of ground tracks

## Sample solutions

### Case 3

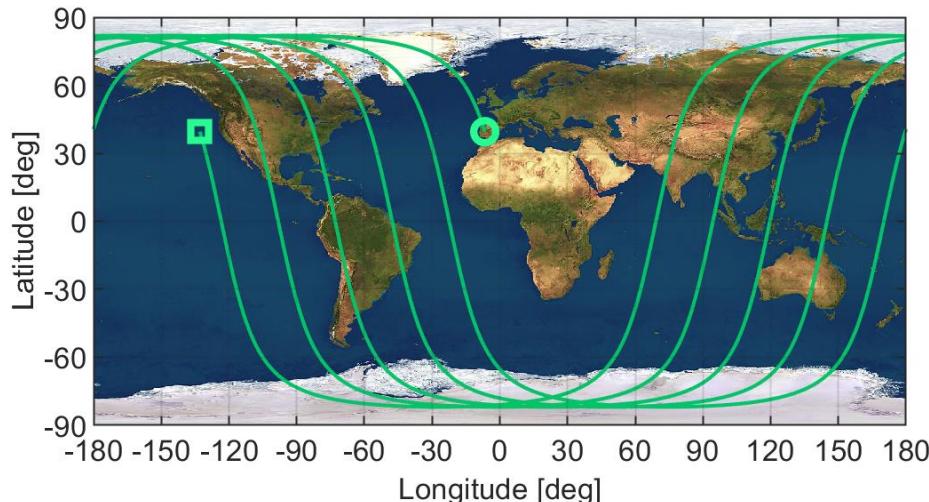

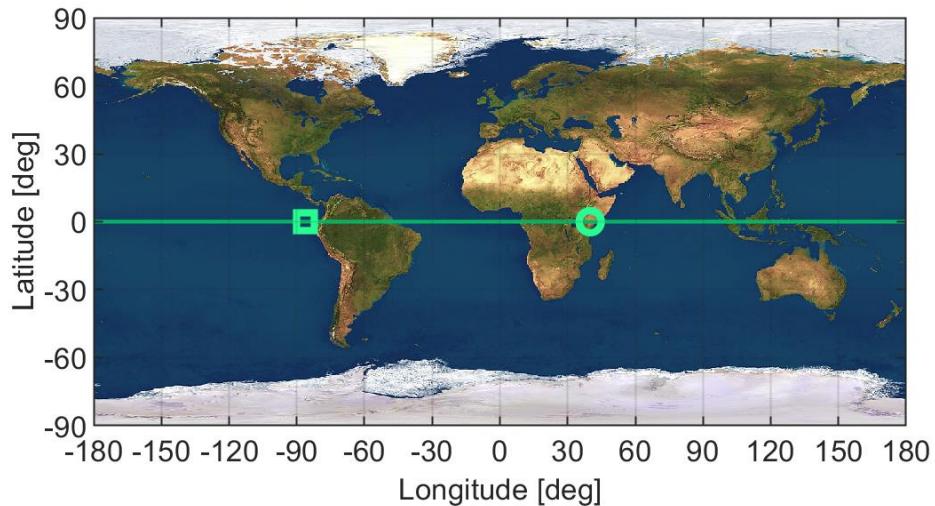

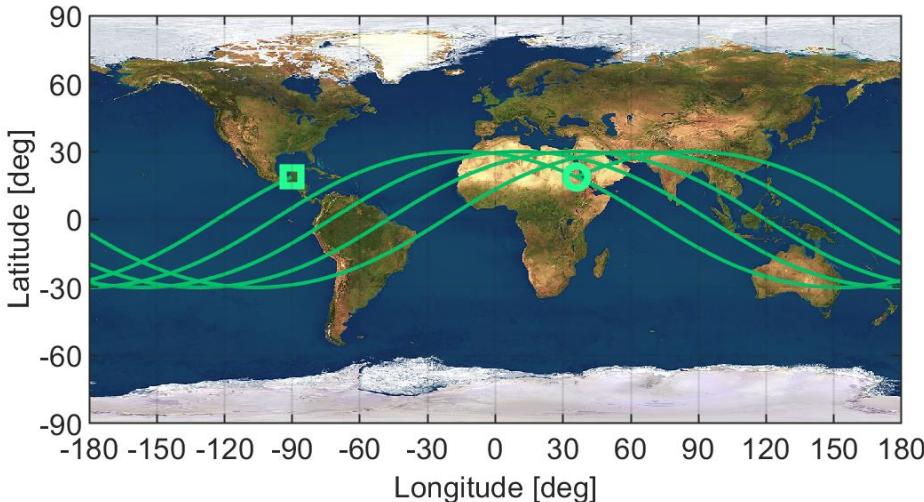

$$a = 7171.010 \text{ km}, e = 0$$

$$\Omega = 0 \text{ deg}, \omega = 40 \text{ deg}, f_0 = 0 \text{ deg}$$

$$\theta_G(t_0) = 0 \text{ deg}$$

5 orbits

$$i = 30 \text{ deg}$$

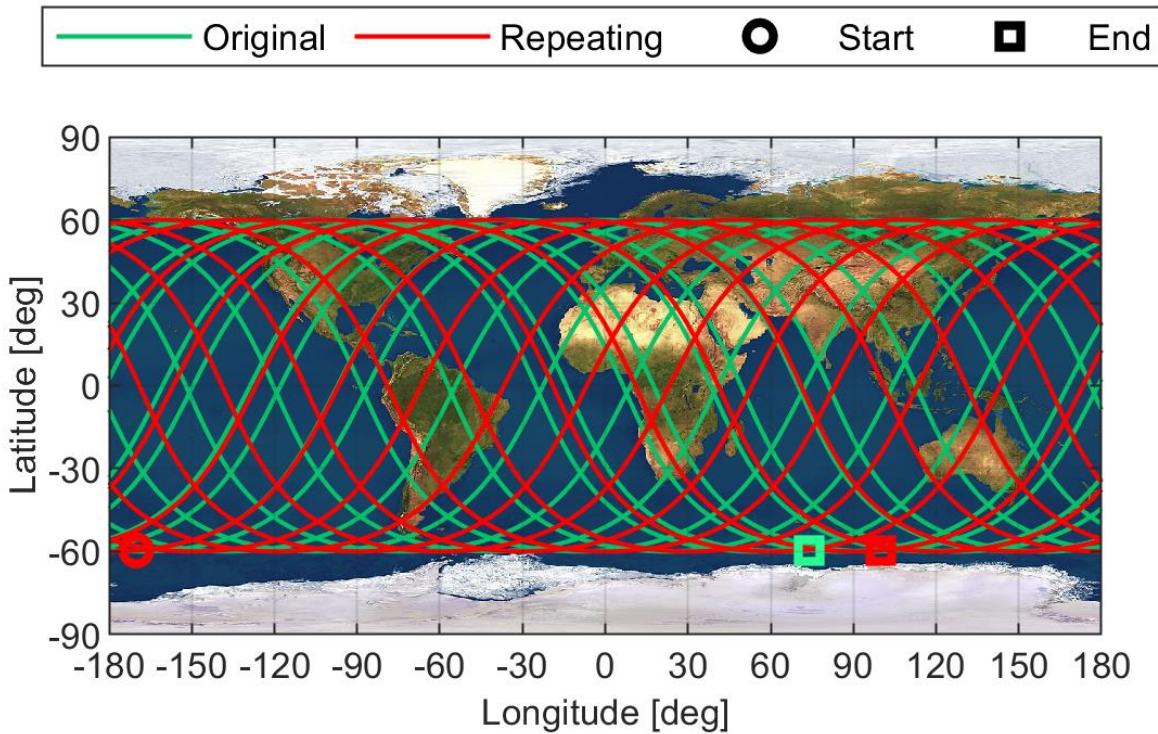

# Exercise 2: Design of repeating ground tracks

## Exercise 2: Design of repeating ground tracks

1. Implement a function that computes the required  $a$  for a repeating ground track with  $k$  satellite revolutions and  $m$  Earth revolutions.
2. Modify the semimajor axis of the orbits in [Exercise 1](#) to get repeating ground tracks with:
  - **Case 1:**  $k = 12, m = 1$
  - **Case 2 (Molniya orbit):**  $k = 2, m = 1$
  - **Case 3 (circular LEOs):**
    - For  $i = 0$  deg:  $k = 20, m = 2$
    - For  $i = 30$  deg:  $k = 29, m = 2$
    - For  $i = 98$  deg:  $k = 15, m = 1$
3. Compute the semimajor axis for a GEO (with  $e = 0, i = \Omega = \omega = 0$  deg,  $f_0 = 20$  deg). Remember that satellites in GEO remain stationary over a point of the equator, so  $m = k = 1$ .
4. Plot each repeating ground track together with the original one and compare them

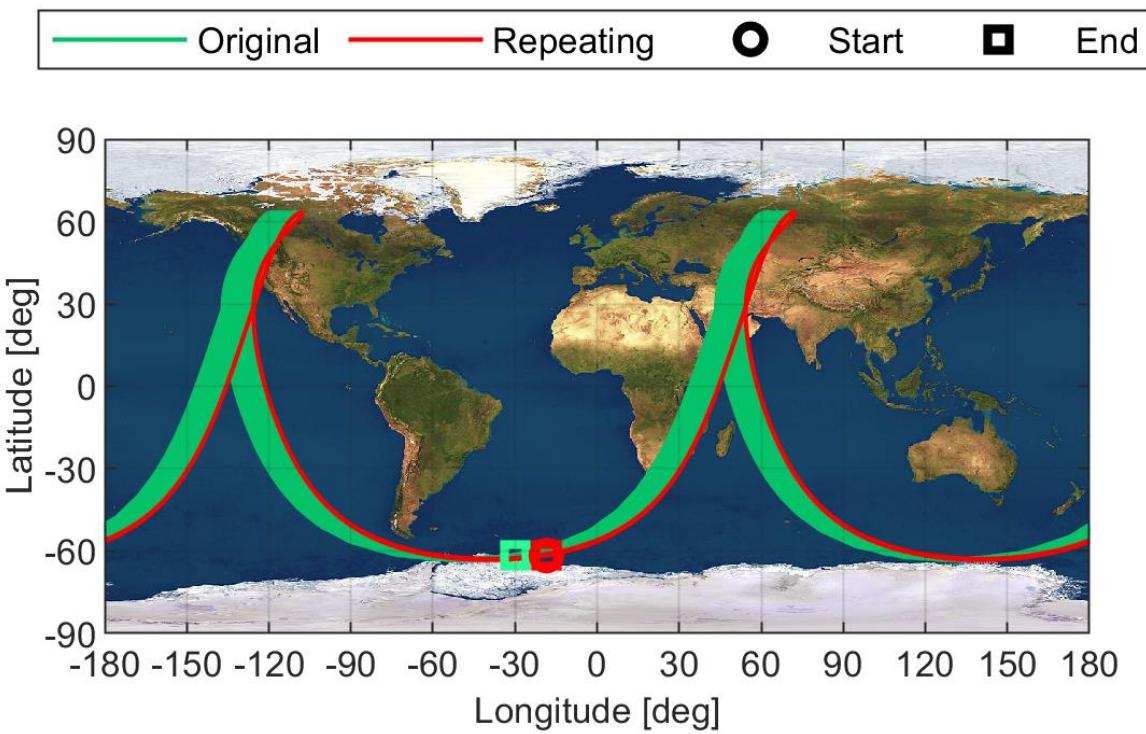

# Exercise 2: Design of repeating ground tracks

## Sample solutions

### Case 1

$a = 8350 \text{ km}$ ,  $e = 0.19760$ ,  $i = 60 \text{ deg}$   
 $\Omega = 270 \text{ deg}$ ,  $\omega = 45 \text{ deg}$ ,  $f_0 = 230 \text{ deg}$   
 $\theta_G(t_0) = 0 \text{ deg}$ , 15 orbits  
 $a_{\text{rep}} = 8044.702 \text{ km}$ ,  $k = 12$ ,  $m = 1$

### Case 2

$a = 26600 \text{ km}$ ,  $e = 0.74$ ,  $i = 63.4 \text{ deg}$   
 $\Omega = 50 \text{ deg}$ ,  $\omega = 280 \text{ deg}$ ,  $f_0 = 0 \text{ deg}$   
 $\theta_G(t_0) = 0 \text{ deg}$ , 30 orbits  
 $a_{\text{rep}} = 26563.020 \text{ km}$ ,  $k = 2$ ,  $m = 1$

# Exercise 2: Design of repeating ground tracks

## Sample solutions

### Case 3

$$a = 7171.010 \text{ km}, e = 0$$

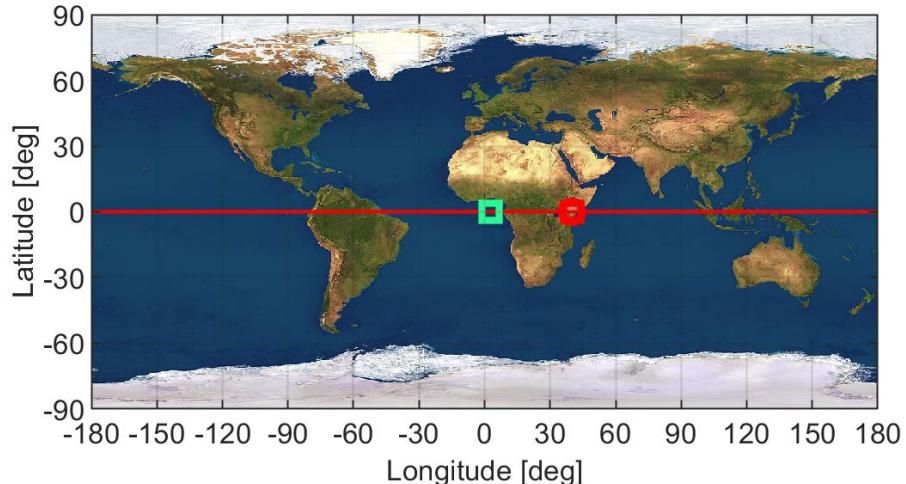

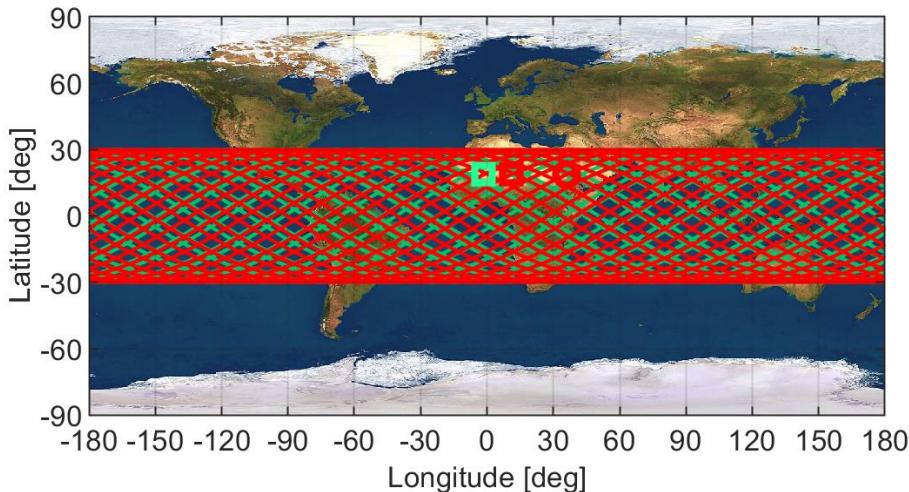

$$\Omega = 0 \text{ deg}, \omega = 40 \text{ deg}, f_0 = 0 \text{ deg}$$

$$\theta_G(t_0) = 0 \text{ deg}$$

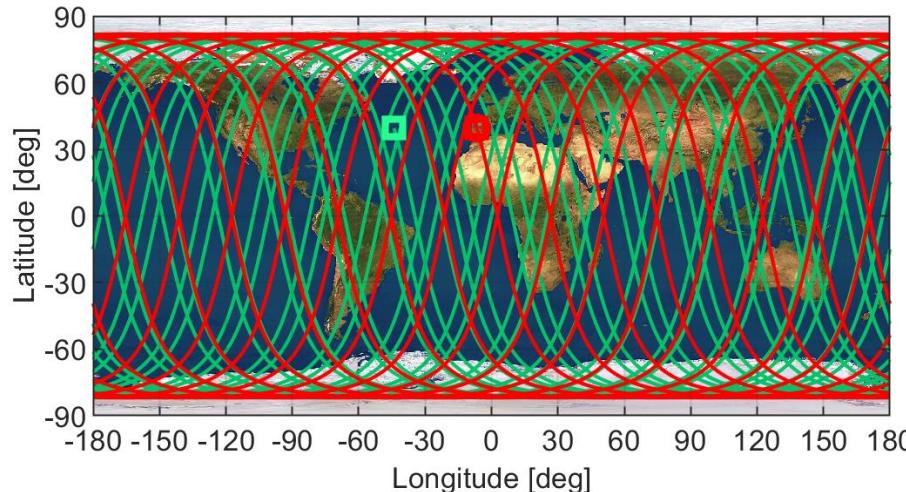

30 orbits

$$i = 30 \text{ deg}$$

$$a_{\text{rep}} = 7091.185 \text{ km}, k = 29, m = 2$$

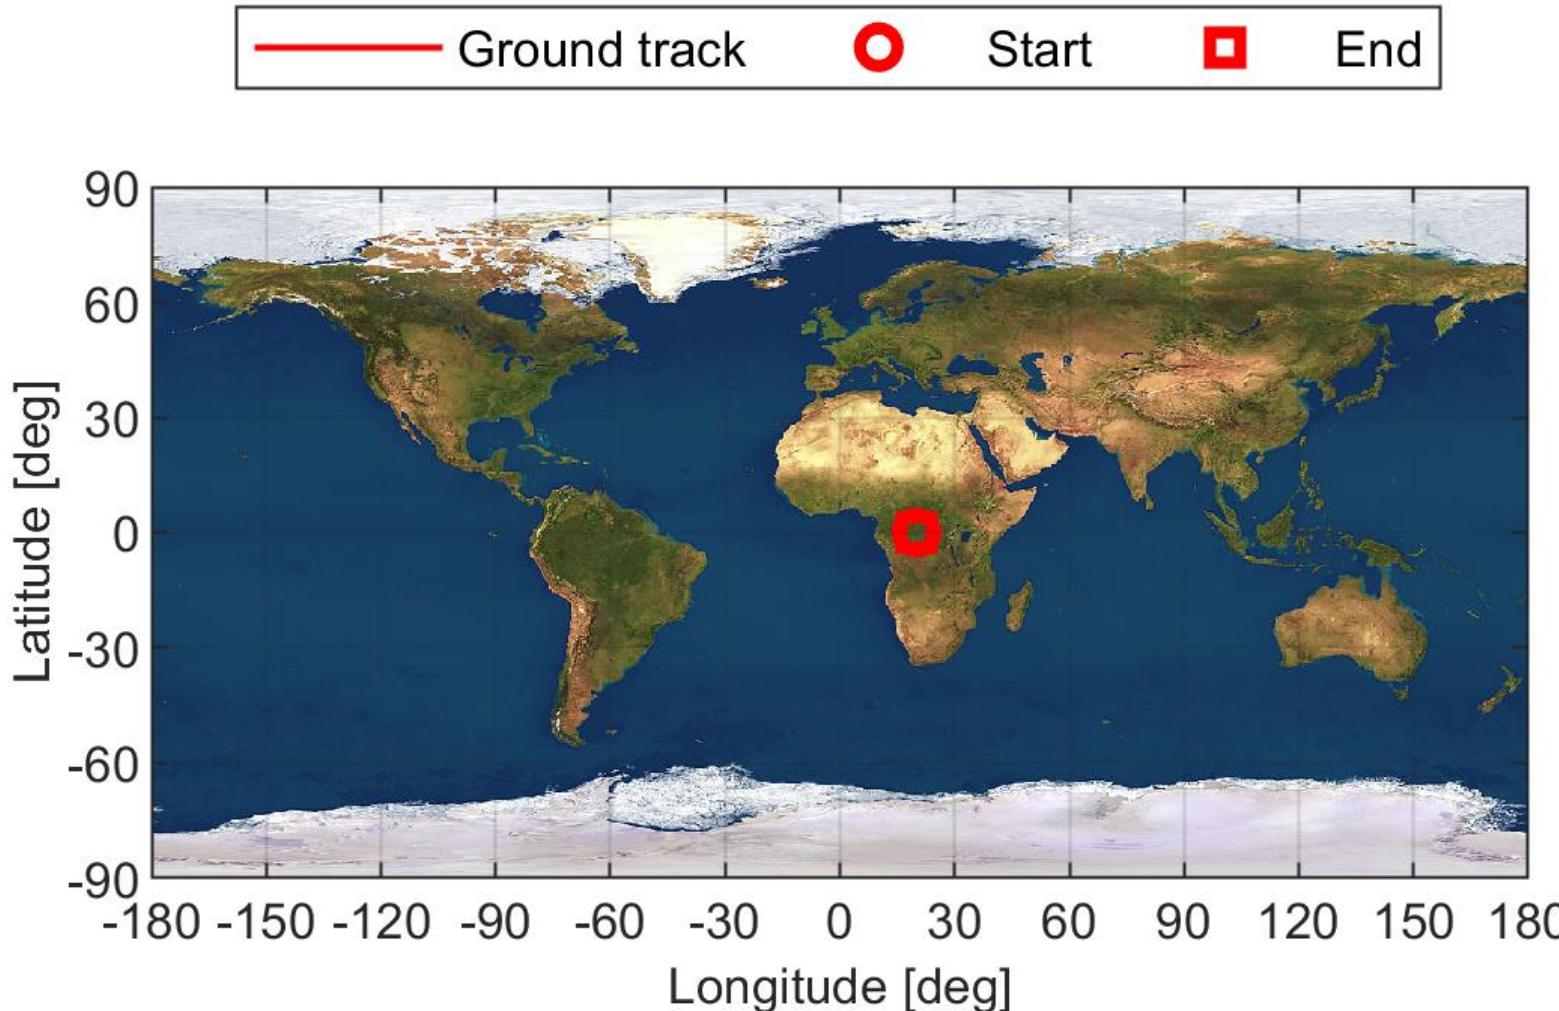

$$\begin{aligned} i &= 0 \text{ deg} \\ a_{\text{rep}} &= 9084.425 \text{ km} \\ k &= 20, m = 2 \end{aligned}$$

$$\begin{aligned} i &= 98 \text{ deg} \\ a_{\text{rep}} &= 6932.714 \text{ km} \\ k &= 15, m = 1 \end{aligned}$$

# Exercise 2: Design of repeating ground tracks

Sample solutions

**GEO**

$a_{\text{rep}} = 42166.167 \text{ km}$ ,  $e = 0$ ,  $i = 0 \text{ deg}$   
 $\Omega = 0 \text{ deg}$ ,  $\omega = 0 \text{ deg}$ ,  $f_0 = 20 \text{ deg}$   
 $\theta_G(t_0) = 0 \text{ deg}$ , 500 orbits

# Repeating ground track with perturbations

## Nodal periods

- Previous results correspond to the **unperturbed 2BP**.
- The repeating ground track condition can be generalized introducing the **nodal periods for satellite and Earth** [2]:
  - Satellite nodal period  $\tilde{T}$ : Time between two successive equator crossings.
  - Greenwich nodal period  $\tilde{T}_E$ : Earth's rotation period with respect to the ascending node.
- $\tilde{T}$  and  $\tilde{T}_E$  are constant and equal to  $T$  and  $T_E$  in the 2BP, but may change under other perturbations ( $J_2$ , atmospheric drag, etc.)
- Same as before, *the condition for repeating ground track is that the ratio of the periods must be a rational number:*

$$\frac{\tilde{T}}{\tilde{T}_E} = \frac{m}{k} \quad \text{with } k, m \in \mathbb{N}$$

[2] Vallado, D.A. *Fundamental of Astrodynamics and Applications*, 4<sup>th</sup> Ed, Microcosm Press, 2013. Section 11.4.2.

# Repeating ground track with perturbations

## Effect of $J_2$

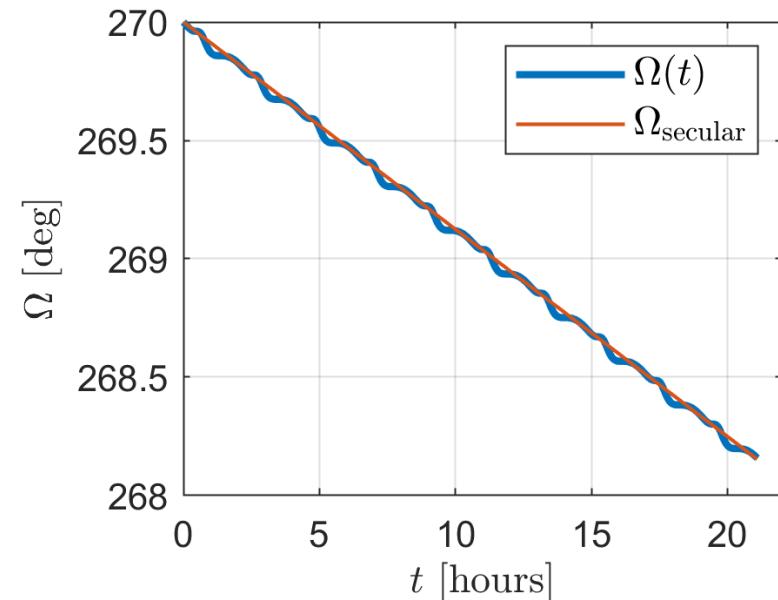

- $J_2$  causes time variations in the Keplerian elements of the orbit [1]:

- Oscillatory short-term variations in all elements.
- **Long-term variations** only for  $\Omega$ ,  $\omega$ , and  $M$ 
  - For  $a$ ,  $e$ , and  $i$  long-term variations average out (mean value 0).
  - The **secular (average long-term)** evolution for  $\Omega$ ,  $\omega$ , and  $M_0 = M(t_0)$  are straight lines with **average change rates** [2]

$$\dot{\Omega} = - \left[ \frac{3}{2} \frac{\sqrt{\mu} J_2 R_e^2}{(1-e^2)^2 a^{7/2}} \right] \cos i$$

$$\dot{\omega} = - \left[ \frac{3}{2} \frac{\sqrt{\mu} J_2 R_e^2}{(1-e^2)^2 a^{7/2}} \right] \left( \frac{5}{2} \sin^2 i - 2 \right)$$

$$\dot{M}_0 = \left[ \frac{3}{2} \frac{\sqrt{\mu} J_2 R_e^2}{(1-e^2)^{3/2} a^{7/2}} \right] \left( 1 - \frac{3}{2} \sin^2 i \right)$$

Evolution of  $\Omega$  for the initial conditions of Exercise 1, case 1

[1] Curtis, H. D.. *Orbital mechanics for engineering students*, Butterworth-Heinemann , 2014

[2] Vallado, D.A. *Fundamental of Astrodynamics and Applications*, 4<sup>th</sup> Ed, Microcosm Press, 2013. Section 11.4.2

# Repeating ground track with perturbations

## Repeating ground track with $J_2$

- The **secular effects of  $J_2$**  modify the nodal periods of satellite and Earth:

- Satellite nodal period  $\tilde{T}$  is modified by  $\dot{\omega}$  and  $\dot{M}_0$

$$\tilde{T} = \frac{2\pi}{n + \dot{M}_0 + \dot{\omega}}$$

- Greenwich nodal period  $\tilde{T}_E$  is modified because the ascending node is changing in time

$$\tilde{T}_E = \frac{2\pi}{\omega_E - \dot{\Omega}}$$

- The **repeating ground track with secular effects of  $J_2$**  becomes an **implicit equation** involving  $a$ ,  $e$ , and  $i$  [2]

$$\frac{m}{k} = \frac{\tilde{T}}{\tilde{T}_E} = \frac{\omega_E - \dot{\Omega}}{n + \dot{\omega} + \dot{M}_0}$$

- Keep in mind that this solution only accounts for the **secular effects**.

[2] Vallado, D.A. *Fundamental of Astrodynamics and Applications*, 4<sup>th</sup> Ed, Microcosm Press, 2013. Section 11.4.2.

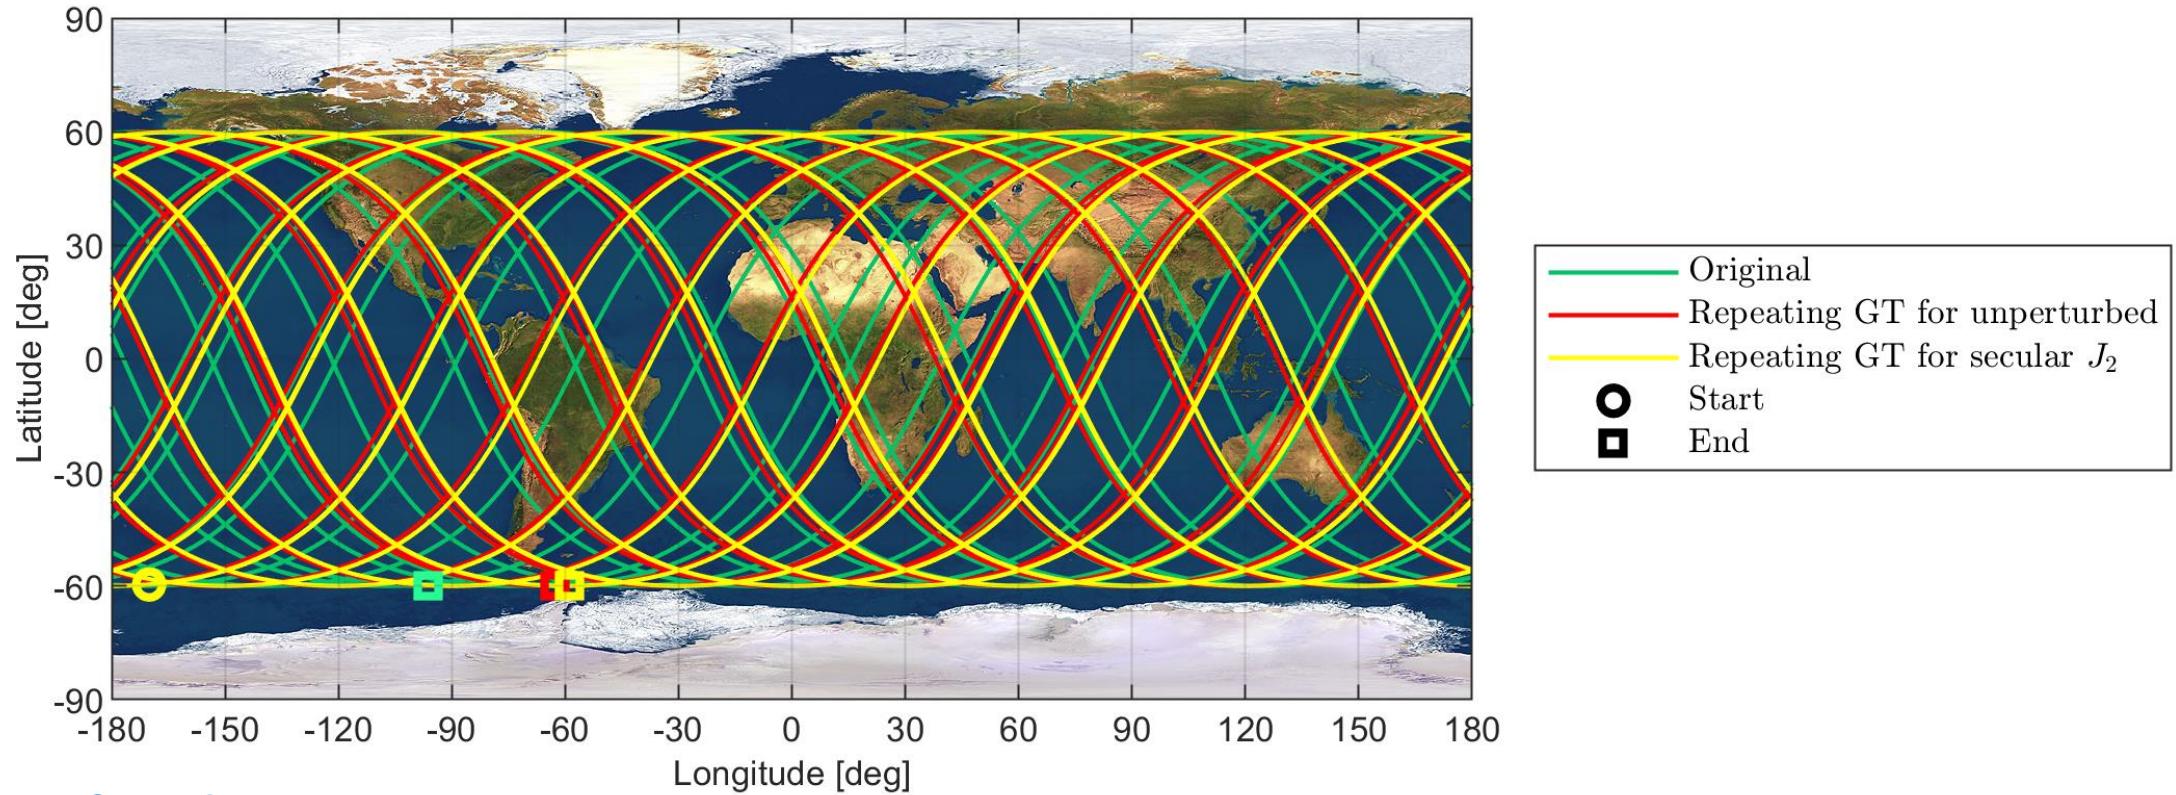

# Exercise 3: Ground tracks with $J_2$

## Exercise 3: Ground tracks with $J_2$

1. Modify function `groundTrack` from [Exercise 1](#) to include the  $J_2$  perturbation
  - Use  $J_2$  value from `astroConstants.m` (identifier 9)
  - You can reuse the code for orbit propagation from the previous module
2. Implement a new function to compute the required semimajor axis  $a$  for a repeating ground track with secular  $J_2$  effects, with  $k$  satellite revolutions and  $m$  Earth revolutions
  - **Hint:** Solve the implicit equation in  $a$  using `fzero` or `fsolve`
3. Repeat the previous test cases, adding  $J_2$  effects
  - Plot together the nominal GT ([Exercise 1](#)) and the repeating GT obtained for unperturbed orbit ([Exercise 2](#)), but including  $J_2$  in the orbit propagation
  - Add the new repeating GT obtained from the repeating GT condition with secular  $J_2$  effects
  - Check that the repeating GT for unperturbed orbit no longer closes
  - Does the repeating GT with secular  $J_2$  perfectly close? Why?
  - Is the GT of the GEO still a point under the effect of  $J_2$ ?

# Exercise 3: Ground tracks with $J_2$

## Sample solutions

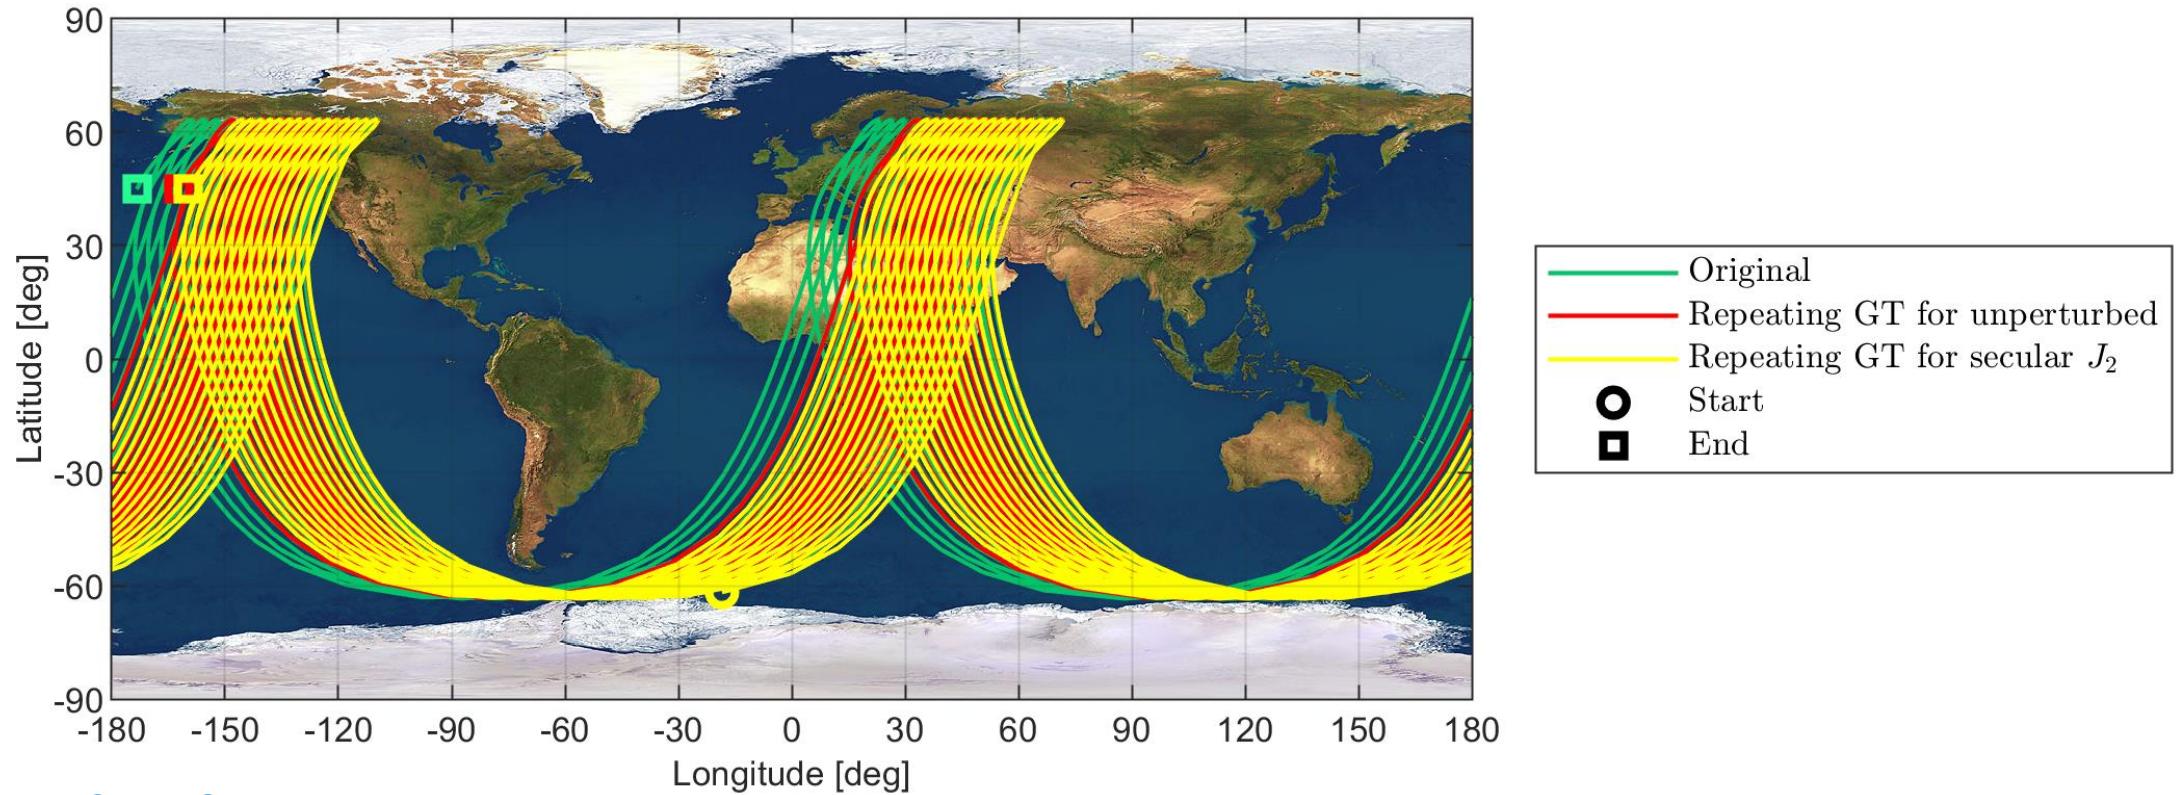

### Case 1

$a = 8350 \text{ km}$ ,  $e = 0.19760$ ,  $i = 60 \text{ deg}$ ,  $\Omega = 270 \text{ deg}$ ,  $\omega = 45 \text{ deg}$ ,  $f_0 = 230 \text{ deg}$   
 $\theta_G(t_0) = 0 \text{ deg}$ , 20 orbits

Repeating ground tracks for  $k = 12$ ,  $m = 1$ :  $a_{\text{rep}}^{\text{unpert}} = 8044.702 \text{ km}$ ,  $a_{\text{rep}}^{\text{sec } J_2} = 8008.866 \text{ km}$

# Exercise 3: Ground tracks with $J_2$

Sample solutions

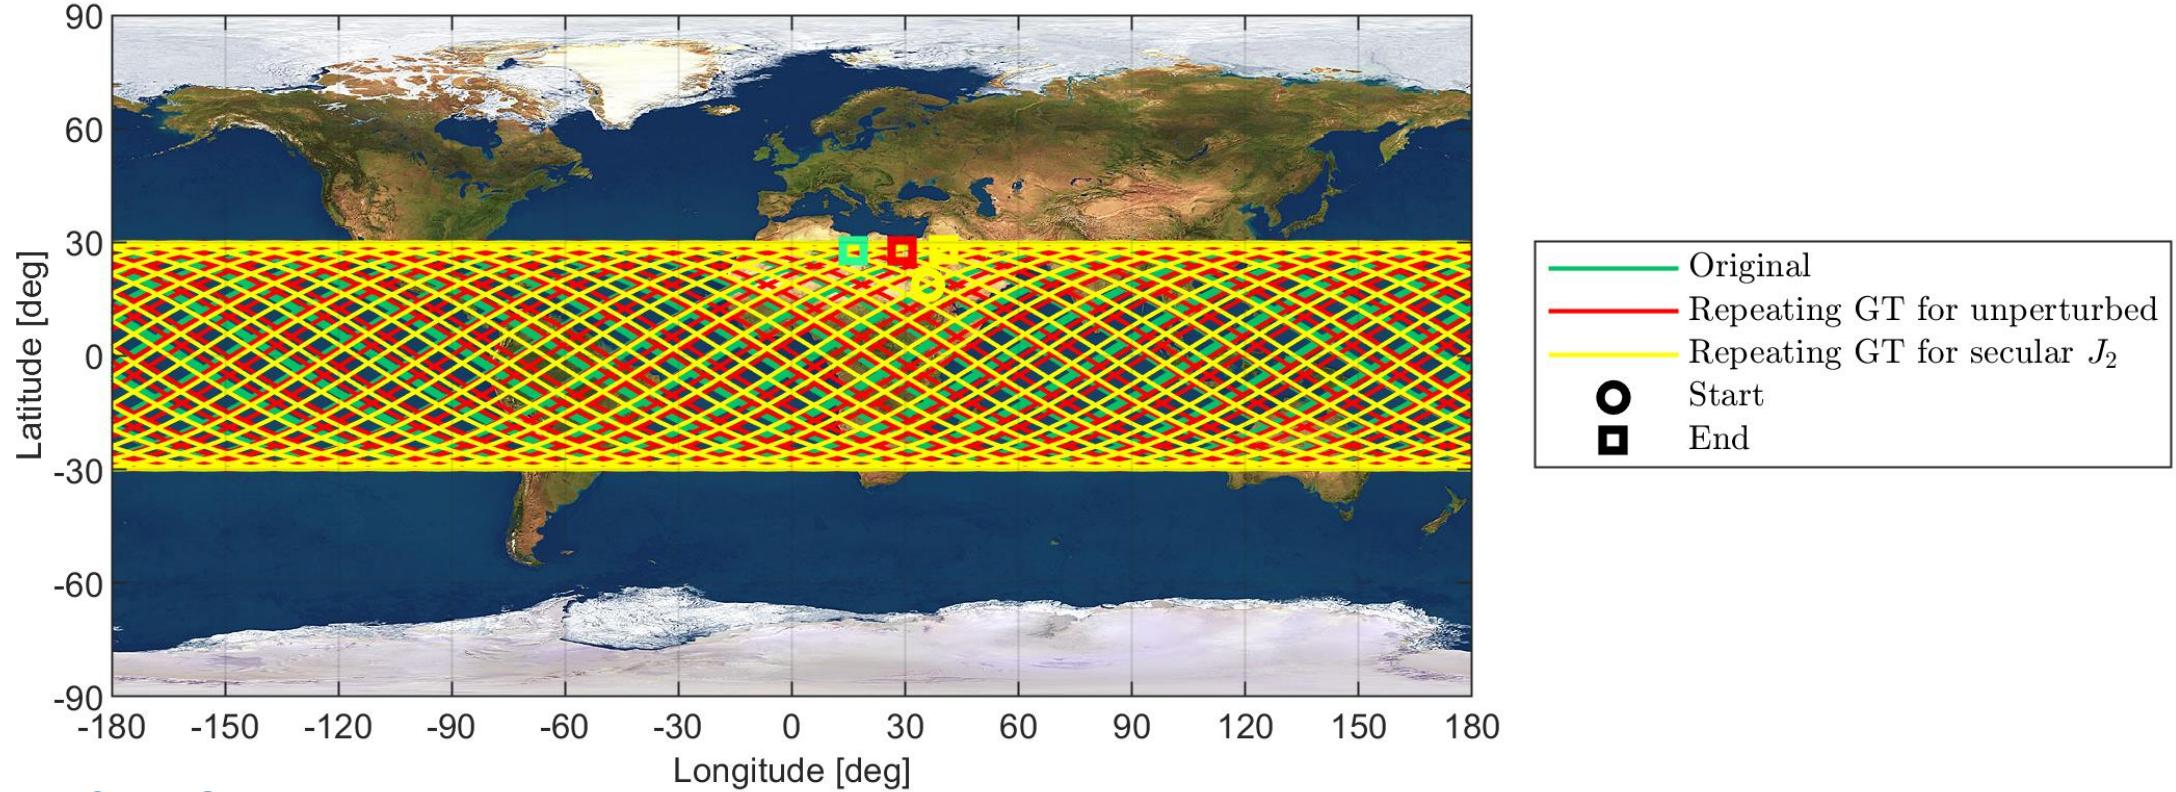

## Case 2

$a = 26600 \text{ km}$ ,  $e = 0.74$ ,  $i = 63.4 \text{ deg}$ ,  $\Omega = 50 \text{ deg}$ ,  $\omega = 280 \text{ deg}$ ,  $f_0 = 0 \text{ deg}$   
 $\theta_G(t_0) = 0 \text{ deg}$ , 30 orbits

Repeating ground tracks for  $k = 2$ ,  $m = 1$ :  $a_{\text{rep}}^{\text{unpert}} = 26563.020 \text{ km}$ ,  $a_{\text{rep}}^{\text{sec } J_2} = 26554.703 \text{ km}$

# Exercise 3: Ground tracks with $J_2$

## Sample solutions

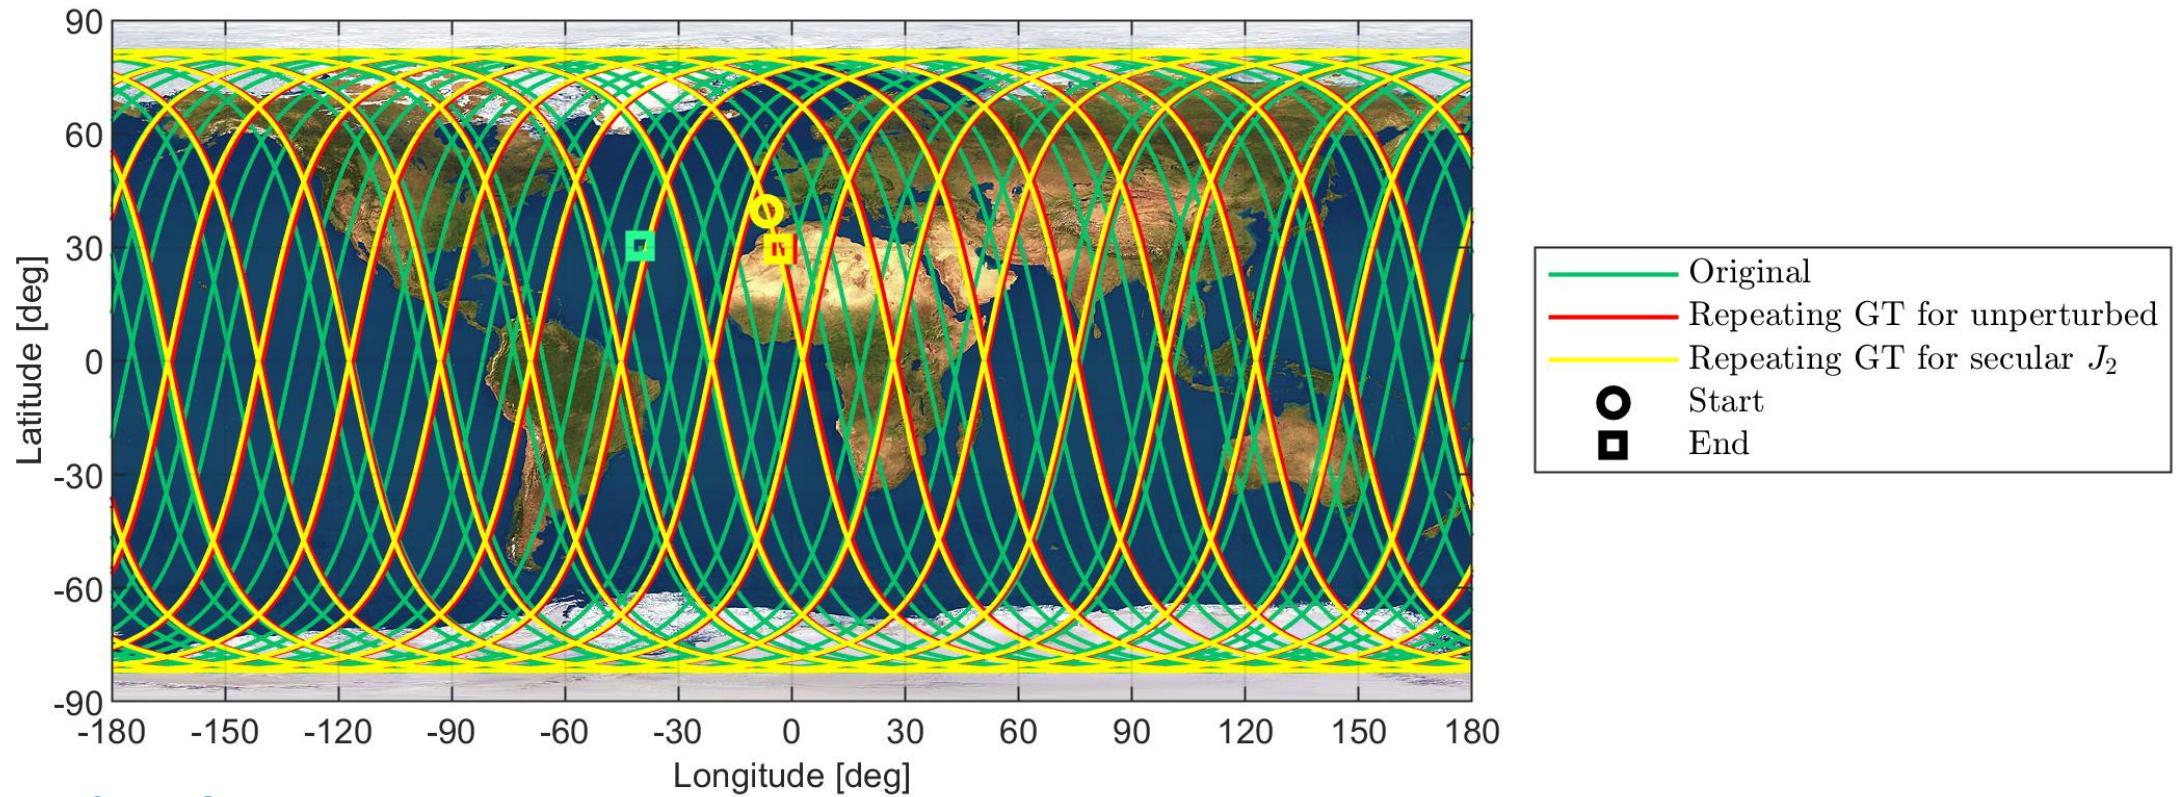

### Case 3

$a = 7171.01 \text{ km}$ ,  $e = 0$ ,  $i = 30 \text{ deg}$ ,  $\Omega = 0 \text{ deg}$ ,  $\omega = 40 \text{ deg}$ ,  $f_0 = 0 \text{ deg}$   
 $\theta_G(t_0) = 0 \text{ deg}$ , 30 orbits

Repeating ground tracks for  $k = 29$ ,  $m = 2$ :  $a_{\text{rep}}^{\text{unpert}} = 7091.185 \text{ km}$ ,  $a_{\text{rep}}^{\text{sec } J_2} = 7024.353 \text{ km}$

# Exercise 3: Ground tracks with $J_2$

Sample solutions

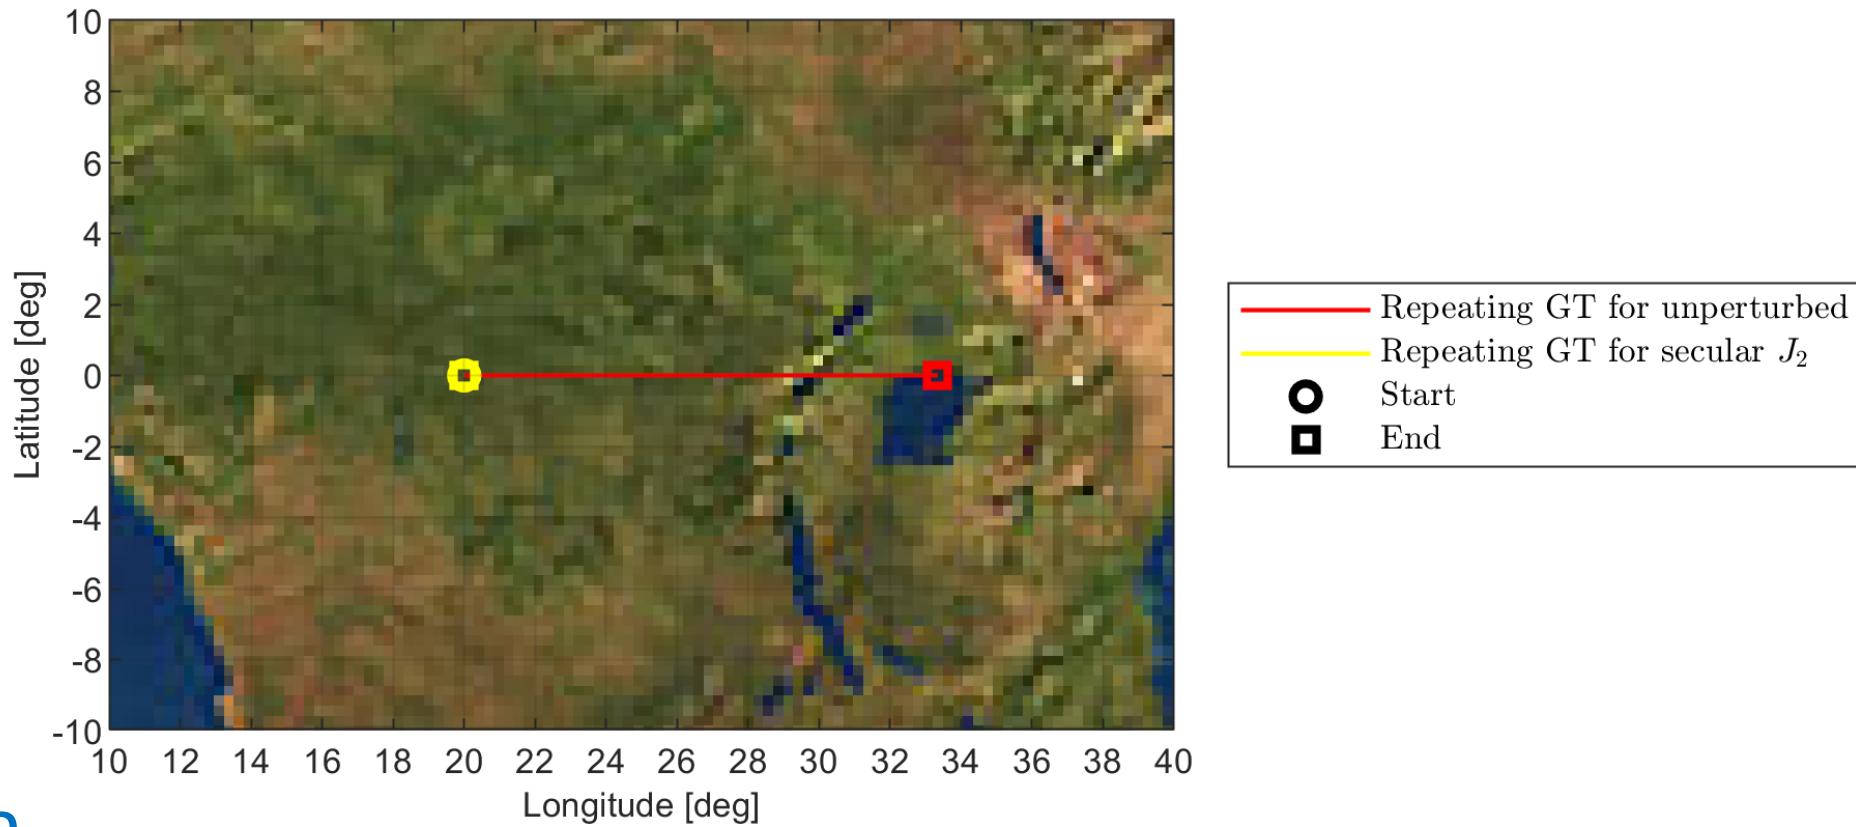

## Case 3

$a = 7171.01 \text{ km}$ ,  $e = 0$ ,  $i = 98 \text{ deg}$ ,  $\Omega = 0 \text{ deg}$ ,  $\omega = 40 \text{ deg}$ ,  $f_0 = 0 \text{ deg}$   
 $\theta_G(t_0) = 0 \text{ deg}$ , 30 orbits

Repeating ground tracks for  $k = 15$ ,  $m = 1$ :  $a_{\text{rep}}^{\text{unpert}} = 6932.714 \text{ km}$ ,  $a_{\text{rep}}^{\text{sec } J_2} = 6940.081 \text{ km}$

# Exercise 3: Ground tracks with $J_2$

Sample solutions

**GEO**

$$e = 0, i = 0 \text{ deg}, \Omega = 0 \text{ deg}, \omega = 0 \text{ deg}, f_0 = 20 \text{ deg}$$

$$\theta_G(t_0) = 0 \text{ deg}, 500 \text{ orbits}$$

Repeating ground tracks for  $k = 1, m = 1$ :  $a_{\text{rep}}^{\text{unpert}} = 42166.167 \text{ km}$ ,  $a_{\text{rep}}^{\text{sec } J_2} = 42168.251 \text{ km}$
